### The file structure expected by the algorithm

The algorithm provides a computationally costly solution to the problem of classifying unsorted files into groups. **The algorithm does not require that filenames have embedded dates.** But, the algorithm does expect to find files in the following directory structure;

1. a folder Y containing  $m$  subfolders (Z), each subfolder containing a variable set of documents that talk about the same topic Z;
2. a folder X containing a list of  $n$  unsorted documents each one of which needs to be placed in one of the  $m$  Z subfolders.

Graphically, this is what the file structure would look like:

Name	Date modified	Type	Size
 3	2/18/2020 10:14 PM	File folder	
 4	2/18/2020 10:15 PM	File folder	
 5	2/18/2020 10:15 PM	File folder	
 6	2/18/2020 10:15 PM	File folder	
 7	2/18/2020 10:15 PM	File folder	

Name	Date modified	Type	Size
 3_Jim Cobb	2/18/2020 10:14 PM	File folder	
 4_Frank Hardeman	2/18/2020 10:15 PM	File folder	
 5_Palseo	2/18/2020 10:15 PM	File folder	
 6_Owen Jones	2/18/2020 10:15 PM	File folder	
 7_Jet Hicks	2/18/2020 10:15 PM	File folder	

Figure 1 – Different representations of folder Y containing  $m$  subfolders (Z)

But whatever naming criteria one adopts, each subfolder contains the articles that describe a specific event.

Figure 2 –Representation of folder X with  $n$  unsorted files

### The way the algorithm works

The tool runs the Stanford CoreNLP with the annotator NER on each of the  $n$  documents in folder X and constructs an index of similarity based on social actors and NER values. It then computes a summary index of group values (based on social actors and NER values) for the files contained in each Z ( $m$  of them) we construct a summary index. Once the indices are computed, the algorithm compares the similarity value of each of the  $n$  file in X with the index of each Z subfolder to see if the processed document in X belongs to group Z.
